

# CSCI 230 DATA STRUCTURES & ALGORITHMS

## PROJECT 2 GUITAR STRING SIMULATION<sup>1</sup>

CRAFTON HILLS COLLEGE

TOTAL POINTS: 60

### OVERVIEW

In this project, you will write a program to simulate plucking a guitar string using the Karplus-Strong algorithm. This algorithm played a seminal role in the emergence of physically modeled sound synthesis (where a physical description of a musical instrument is used to synthesize sound electronically). The Karplus-Strong models the vibration of a guitar string with a remarkably simple process: Maintain a buffer of displacements; then, repeatedly delete the first displacement from the front of the buffer and append the average of the first two displacements, scaled by an energy dissipation factor, to the end of the buffer. The size of the buffer determines the frequency of the guitar string. To represent a guitar, you will create many guitar strings (of different frequencies), process keystrokes to identify which strings get plucked, superpose the resulting sound waves, and sonify the results. The key data structure needed to perform the Karplus-Strong simulation efficiently is a ring buffer (bounded queue).

### BACKGROUND

**Digital Audio.** Sound waves travel through the air by the changes of air pressure at different moments in time. The stronger the change in pressure, the louder the sound. As the speed of the air pressure increases, the perceived pitch becomes higher. These changes of *amplitude* (loudness) and *frequency* (pitch) are the two principal factors of sound. Digital recording of sound is performed at regular time intervals, when the amplitude of an analog sound wave is recorded, generating a sample. The closer together that samples are recorded, the more accurate the recording becomes. The rate of sample measurement is called the *sampling rate* (or *sampling frequency*). The figure on the right<sup>2</sup> shows how an analog sound wave is sampled at regular time intervals.

<sup>1</sup> Based on <http://nifty.stanford.edu/2012/wayne-guitar-heroine/>

<sup>2</sup> [http://www.indiana.edu/~emusic/etext/digital\\_audio/chapter5\\_sample.shtml](http://www.indiana.edu/~emusic/etext/digital_audio/chapter5_sample.shtml)

**Simulate the plucking of a guitar string.** When a guitar string is plucked, the string vibrates and creates sound. The length of the string determines its fundamental frequency of vibration. We model a guitar string by sampling its displacement (a real number between  $-1/2$  and  $+1/2$ ) at  $N$  equally spaced points (in time), where  $N$  equals the sampling rate (44,100 samples/second) divided by the fundamental frequency, which is the lowest frequency produced by the oscillation of an object (rounding the quotient up to the nearest integer).

- **Plucking the string.** The excitation of the string can contain energy at any frequency. We simulate the excitation with white noise: set each of the  $N$  displacements to a random real number between  $-1/2$  and  $+1/2$ .

- **The resulting vibrations.** After the string is plucked, the string vibrates. The pluck causes a displacement which spreads wave-like over time. The Karplus-Strong algorithm simulates this vibration by maintaining a ring buffer of the  $N$  samples: the algorithm repeatedly deletes the first sample from the buffer and adds to the end of the buffer the average of the first two samples, scaled by an energy decay factor of 0.994.

**Why it works?** The two primary components that make the Karplus-Strong algorithm work are the ring buffer feedback mechanism and the averaging operation.

- **The ring buffer feedback mechanism.** The ring buffer models the medium (a string tied down at both ends) in which the energy travels back and forth. The length of the ring

buffer determines the fundamental frequency of the resulting sound. Sonically, the feedback mechanism reinforces only the fundamental frequency and its harmonics (frequencies at integer multiples of the fundamental). The energy decay factor (.994 in this case) models the slight dissipation in energy as the wave makes a roundtrip through the string.

- **The averaging operation.** The averaging operation serves as a gentle low-pass filter (which removes higher frequencies while allowing lower frequencies to pass, hence the name). Because it is in the path of the feedback, this has the effect of gradually attenuating the higher harmonics while keeping the lower ones, which corresponds closely with how a plucked guitar string sounds.

## PROJECT REQUIREMENTS

### 1. Ring buffer.

- Write a class named `RingBuffer` that models a ring buffer by implementing the following API:
  - `RingBuffer(int capacity)` : creates an empty ring buffer, with given max capacity
  - `RingBuffer()` : creates an empty ring buffer with capacity of 100
  - `int size()` : returns the number of items currently in the buffer
  - `boolean isEmpty()` : returns whether the buffer is empty (size equals zero)
  - `boolean isFull()` : returns whether the buffer is full (size equals max capacity)
  - `void enqueue(double x)` : add item `x` to the end or throws a `RingBufferException` exception if the buffer is full (you can define `RingBufferException` to be a subclass of `Exception`, as a public class nested in the `RingBuffer`)
  - `double dequeue()` : delete and return item from the front; throws a `RingBufferException` exception if the buffer is empty
  - `double peek()` : returns (but do not delete) item from the front
- Implement the ring buffer using a double array. For efficiency, use cyclic wrap-around: Maintain one integer instance variable `first` that stores the index of the least recently inserted item; maintain a second integer instance variable `last` that stores the index one beyond the most recently inserted item. To insert an item, put it at index `last` and increment `last`. To remove an item, take it from index `first` and increment `first`. When either index reaches the end of the array, make it wrap-around by changing the index to 0. *Note: You must implement the ring buffer in this manner to get full credits.*
- Here is an illustration of a ring buffer of capacity 10 with 4 elements:

## 2. Guitar String.

- Write a class named `GuitarString` that models a vibrating guitar string by implementing the following API:
    - `GuitarString(double frequency)`: creates a guitar string of the given frequency, using a sampling rate of 44,100
      - Creates a `RingBuffer` of the desired capacity  $N$  (sampling rate 44,100 divided by `frequency`, rounded up to the nearest integer), and initializes it to represent a guitar string at rest by enqueueing  $N$  zeros.
    - `GuitarString(double[] init)`: creates a guitar string whose size and initial values are given by the array
      - Creates a `RingBuffer` of capacity equal to the size of the array, and initializes the contents of the buffer to the values in the array.
    - `void pluck()`: sets the buffer to white noise
      - Replaces all items in the ring buffer with random values between -0.5 and +0.5.
    - `void tic()`: advances the simulation one time step
      - Applies the Karplus-Strong update: delete the sample at the front of the ring buffer and add to the end of the ring buffer the average of the first two samples, multiplied by the energy decay factor of 0.994.
    - `double sample()`: returns the current sample
      - Return the value of the item at the front of the ring buffer.
    - `int time()`: return number of tics
      - Return the total number of times `tic()` was called.
3. Write a program `GuitarHelo` that is similar to `GuitarHeroLite` but supports a total of 37 notes on the chromatic scale from 110 Hz to 880 Hz. The program should also plot the sound wave in real-time.
- `GuitarHeroLite.java` is a sample `GuitarString` client that plays the guitar in real-time, using the keyboard to input notes. When the user types the lowercase letter 'a' or 'c', the program plucks the corresponding string. Since the

combined result of several sound waves is the superposition of the individual sound waves, we play the sum of all string samples.

```
public class GuitarHeroLite {
    public static void main(String[] args) {

        // create two guitar strings, for concert A and C
        double CONCERT_A = 440.0;
        double CONCERT_C = CONCERT_A * Math.pow(1.05956, 3.0);
        GuitarString stringA = new GuitarString(CONCERT_A);
        GuitarString stringC = new GuitarString(CONCERT_C);

        while (true) {

            // check if the user has typed a key; if so, process it
            if (StdDraw.hasNextKeyTyped()) {
                char key = StdDraw.nextKeyTyped();
                if (key == 'a') { stringA.pluck(); }
                else if (key == 'c') { stringC.pluck(); }
            }

            // compute the superposition of samples
            double sample = stringA.sample() + stringC.sample();

            // play the sample on standard audio
            StdAudio.play(sample);

            // advance the simulation of each guitar string by one step
            stringA.tic();
            stringC.tic();
        }
    }
}
```

- In general, make the  $i^{\text{th}}$  character of the string below play the  $i$  note.

```
String keyboard = "q2we4r5ty7u8i9op-[=zxdcfvgbnjmk,.;/' ";
```

This keyboard arrangement imitates a piano keyboard: The "white keys" are on the qwerty and zxcv rows and the "black keys" on the 12345 and asdf rows of the keyboard.

- The  $i^{\text{th}}$  character of the string corresponds to a frequency of  $440 \times 1.05956^{(i-24)}$ , so that the character 'q' is approximately 110Hz, 'i' is close to 220Hz, 'v' is close to 440Hz, and ' ' is close to 880Hz. Don't even think of including 37 individual

GuitarString variables or a 37-way if statement! Instead, create an array of 37 GuitarString objects and use `keyboard.indexOf(key)` to figure out which key was typed. Make sure your program does not crash if a key is played that is not one of your 37 notes.

- Plots the sound wave in real-time, as the user is playing the keyboard guitar. The output should look something like this, but change over time.

- **Hint:** Use a `RingBuffer` to store the sound samples that have been generated. Drawing methods of the `StdDraw` class are described here: <http://introcs.cs.princeton.edu/java/stdlib/javadoc/StdDraw.html> Use the `StdDraw.line` method to draw the sound wave (you can calculate the coordinates using the samples stored in the ring buffer). To avoid significant time delay when the curve is being draw, use the `StdDraw.show` method to display the animation. For example:

```
StdDraw.show(10);
StdDraw.clear();
// use StdDraw.line to generate the sound waveform
StdDraw.show(10);
```

4. Object-oriented design principles, including data encapsulation and information hiding, should be used.
5. Code should be well-documented, including all classes and class members. Follow the style guidelines for the Javadoc tool (<http://www.oracle.com/technetwork/articles/java/index-137868.html>).
6. All source code and runnable jar file must be submitted properly on Blackboard. (IMPORTANT: if I am not able to read your source files and/or run your executable, your project will not be graded. It is your responsibility to make sure all files are submitted correctly before the deadline.)

### Creating a New Runnable JAR File

To create a new runnable JAR file in the Eclipse workbench:

- From the menu bar's **File** menu, select **Export**.
- Expand the Java node and select **Runnable JAR** file. Click Next.
- In the Runnable JAR File Specification page, select a 'Java Application' launch configuration to use to create a runnable JAR.
- In the **Export destination** field, either type or click **Browse** to select a location for the JAR file.
- Select an appropriate library handling strategy. Choose "Package required libraries into generated JAR".
- Be sure to test the runnable JAR file by opening it.

### WHAT YOU NEED TO SUBMIT FOR THE PROJECT:

---

- A report containing the following items:
  - Your name
  - A brief discussion of your project experience
    - Did you enjoy this project? What problems did you encounter?
    - What did you get out from the project?
    - How did you find the project (too easy, easy, just right, difficult, too difficult)?
    - What type of help/references did you use in your project (e.g. book, web sites, classmates, tutors)? List their names.

### GRADING CRITERIA

---

- Satisfaction of project requirements (47 points)
- Report (3 points)
- Documentation and coding style (10 points)
  - Provide sufficient documentation in the source code. **Each class and method should be documented clearly.**

- Your name should be present in each user-defined class.
- Use descriptive identifiers.
- Use proper spacing and indentation (refer to the textbook's program style).
